PHD 5127 Dose Optimization I

Case Study III

1) 5 mg Dexamethasone were administered to a 40-year old (75 kg) patient through an IV bolus injection. The clearance and volume of distribution of dexamethasone are 3.7 mL/min/kg and 0.82 L/kg, respectively. Assume one-compartment body model and first-order elimination.

Calculate \( k_e \), half-life \( (t_{1/2}) \), and \( AUC_\infty \)

\[
V_d = 61.5 \, L
\]

\[
CL = 16.65 \, \frac{L}{h}
\]

\[
k_e = \frac{16.65 \, \frac{L}{h}}{61.5 \, L} = 0.271 \, \frac{1}{h}
\]

\[
t_{1/2} = \frac{\ln(2)}{0.271 \, \frac{1}{h}} = 2.56 \, h
\]

\[
AUC_\infty = \frac{Dose}{CL} = \frac{5 \, mg \cdot h}{16.65 \, L} = 0.3 \, \frac{mg \cdot h}{L}
\]

2) A new analysis technique has enabled you to measure the drug concentration before and after the blood passes the liver. The plasma concentrations before and after the liver was passed were 6.5 and 2.4 mg/mL, respectively.

Calculate the hepatic clearance (assume a liver blood flow of 1450 mL/min)

\[
CL_H = 87 \, \frac{L}{h} \cdot \frac{6.5 \, mg/mL - 2.4 \, mg/mL}{6.5 \, mg/mL} = 54.88 \, \frac{L}{h}
\]

3) TRUE (T) or FALSE (F)

T F

A change in the clearance will affect the volume of distribution

T F

Clearance and volume of distribution are dependent on each other

T F

If, for a given drug, \( Q_H \gg \gg f_u \cdot CL_{int} \), the drug is considered to be a high extraction drug

T F

Enzyme induction always affects the hepatic clearance
Plasma protein binding is dependent on liver blood flow

Enzyme induction affects the hepatic clearance of low extraction drug

Drugs with a high volume of distribution are always low extraction drugs

4) Define enzyme induction and enzyme inhibition and their potential consequences on pharmacotherapy

Refer to the video of the case study for the definitions

Dose and dosing regimen might have to be adjusted.

5) Assume an intrinsic clearance of i) 40000 L/min and ii) 0.04 L/min. The plasma protein binding and liver blood flow are 60% and 80 L/min, respectively, for both situations.

a) Calculate the hepatic clearance for both situations

   I. High extraction drug

   \[ CL_H = \frac{Q_H \times f_d \times CL_{int}}{Q_H + f_d \times CL_{int}} = \frac{80 \text{ L/min} \times 0.4 \times 40000 \text{ L/min}}{80 \text{ L/min} + 0.4 \times 40000 \text{ L/min}} = 79.6 \text{ L/min} \approx Q_H = 80 \text{ L/min} \]

   \[ CL_H = \frac{Q_H \times f_d \times CL_{int}}{Q_H + f_d \times CL_{int}} = \frac{80 \text{ L/min} \times 0.4 \times 0.04 \text{ L/min}}{80 \text{ L/min} + 0.4 \times 0.04 \text{ L/min}} = 0.016 \text{ L/min} \approx f_d \times CL_{int} \]

b) Predict the effect of a change in A) plasma protein binding and B) liver blood flow for both situations.

   I. High extraction drug

      a. No effect \( CL_H \approx Q_H \)

      b. \( CL_H \) will either increase or decrease

   II. Low extraction drug

      a. \( CL_H \) will either increase or decrease \( CL_H \approx f_d \times CL_{int} \)

      b. No effect
